

How to install and remove software using the APT command

to install the desired package by running "sudo apt install package-name". To remove software, use "sudo apt remove package-name" to uninstall it while keeping its configuration files, or "sudo apt purge package-name" to completely remove both the package and its configuration files.

- `sudo apt install "package-name"`
- `sudo apt remove "package-name"`
- `sudo apt purge "package-name"`

How to create a shell script

Step 1 Create the file

Open a terminal and create a new file with a .sh extension

Step 2 Add Shell declaration

Write the shebang line as the very first line of the file to specify which shell should interpret the script. The most common is `#!/bin/bash` or the more portable `#!/usr/bin/env bash`

Step 3 Add your code

Enter the shell commands you want to execute, exactly as you would type them in the terminal. This is the main body of your script where the actual work happens.

Step 4 Run the Script

Make the file executable with `chmod +x filename.sh`, then run it by typing `./filename.sh` (or use `bash filename.sh` if you prefer not to change permissions).
